

Lecture 12: Measurement Error BIO144 Data Analysis in Biology

Owen Petchey, Stephanie Muff & Erik Willems

University of Zurich

22 May, 2023

Lecture 12: Measurement Error 1 / 23

Overview

- ightharpoonup Measurement error (ME) in one or more explanatory variable(s) (x)
- Effects of ME on model parameters
- ► When do you have to worry?
- ► An example of a method to correct for ME

Lecture 12: Measurement Error 2 / 23

Course material covered today

The lecture material is partially based on:

► Chapter 6.1 in "Lineare regression" (BC reading)

Lecture 12: Measurement Error

Sources of measurement error (ME)

- ▶ **Measurement imprecision** in the field or in the lab (length, weight, blood pressure, etc.).
- ► Errors due to **incomplete** or **inaccurate observations** (e.g., self-reported dietary aspects, health history).
- Rounding error, digit preference.
- Classification error (e.g., exposure or disease classification).

"Error" is often used synonymous to "uncertainty".

Lecture 12: Measurement Error 4 / 23

Yet another assumption...

It is an implicit assumption of most statistical tests that explanatory variables are measured or estimated without error. This is true for:

- correlation
- regression and ANOVA
- Generalized Linear Models (e.g. Poison and binomial GLMs)

Violation of this assumption may lead to:

- biased parameter estimates, standard errors, and thus wrong p-values
- incorrect (relative) variable importance, and thus even more misguided conclusions

Standard statistics textbooks often do not mention this assumption at all!

Lecture 12: Measurement Error 5 / 23

Classical measurement error

A very common type of error:

Let $\underline{x_i}$ be the <u>correct but unobserved</u> variable and w_i the observed variable with error u_i . Then the **classical ME model** is:

$$\underline{w_i} = \underline{x_i} + \underline{u_i}, \qquad u_i \sim \underline{N(0, \sigma_u^2)}$$

Examples: Inaccurate measurements of a <u>concentration</u>, a <u>mass</u>, a <u>length</u> etc. \rightarrow the observed value w_i varies around the true value x_i .

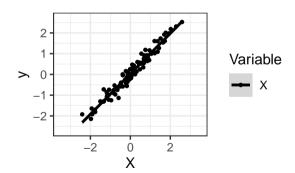

Lecture 12: Measurement Error 6 / 23

Find regression parameters β_0 and β_x for the model with explanatory variable ${\bf x}$:

$$\underline{y_i} = 0 + \underline{1} \cdot \underline{x_i} + \epsilon_i, \qquad \epsilon_i \sim N(0, \sigma^2)$$

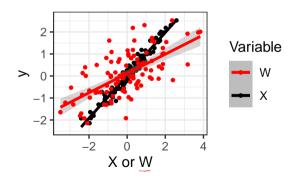

Lecture 12: Measurement Error 7 / 23

However, assume that only an erroneous proxy $\underline{\boldsymbol{w}}$ is observed with classical ME

$$\underline{w_i} = \underline{x_i} + \underline{u_i}, \qquad u_i \sim \underline{N(0, \sigma_u^2)}, \qquad \underline{\sigma_u^2 = \sigma_x^2}$$

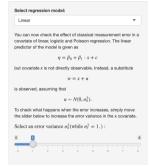

Lecture 12: Measurement Error 8 / 23

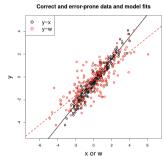

A tool you can play around with...

Illustration in a browser application

Classical measurement error in linear, logit and Poisson regression

The slope parameter of the error prone dataset is estimated as 0.64 (true slope: 1.0).

The residual variance of the error prone model is estimated as 0.89 (true value: 0.25).

Lecture 12: Measurement Error 9 / 23

The "Triple Whammy of Measurement Error"

(Carroll et al. 2006)

- 1. Biased parameter estimates
- 2. Loss of power to detect signals
- 3. Masks important features of the data, making graphical model inspection difficult

Lecture 12: Measurement Error 10 / 23

How to correct for ME?

Generally, to correct for the error you need an error model and knowledge of the error model parameters.

Example: If classical error $\underline{w_i} = \underline{x_i} + \underline{u_i}$ with $u_i \sim N(0, \sigma_u^2)$ is present, knowledge of the **error variance** σ_u^2 is required.

Strategy: Take repeated measurements to estimate the error variance!

- In simple cases, formulas for the bias exist.
- In most cases, such simple relations don't exist, and dedicated error modelling methods are needed.

Lecture 12: Measurement Error 11 / 23

Attenuation in normal linear regression

Given the simple linear regression equation $y_i = \underline{\beta_0} + \underline{\beta_x}x_i + \epsilon_i$ with $w_i = x_i + u_i$. Assume that w_i instead of x_i is used in the regression:

$$\longrightarrow y_i = \beta_0^* + \beta_x^* \underline{w_i} + \epsilon_i$$

The naive slope parameter β_x^* underestimates the true slope β_x by attenuation factor λ :

$$\beta_{\mathsf{x}}^{\star} = \underbrace{\left(\frac{\sigma_{\mathsf{x}}^{2}}{\sigma_{\mathsf{x}}^{2} + \sigma_{\mathsf{u}}^{2}}\right)}_{-1} \beta_{\mathsf{x}}$$

 \rightarrow knowing σ_{ν}^{2} and σ_{x}^{2} , the correct slope can be retrieved!

Example: $\sigma_x^2 = 5$, $\sigma_u^2 = 1$, $\rightarrow \lambda = \frac{5}{5+1} = 0.83$

Error modeling

Two common approaches:

- **SIMEX**: SIMulation EXtrapolation, a heuristic and intuitive idea.
- → **Bayesian methods**: Information about the error enters the model as a *prior*.

Both, however, require that the error model, and its respective parameters (e.g., σ_u^2) are known!

Thus, information about the error mechanism is essential, and potential sources of error must be identified at the planning stages of a study!

Lecture 12: Measurement Error 13 / 23

SIMEX: An intuitive idea

Suggested by Cook & Stefanski (1994), SIMEX takes a two-step approach:

- 1. **Simulation phase:** The error in the data is progressively aggravated in order to determine how the model parameter of interest is affected.
- 2. **Extrapolation phase:** The simulated trend is then extrapolated back to a hypothetical error-free value of the model parameter.

Lecture 12: Measurement Error 14 / 23

Illustration of the SIMEX idea

Parameter of interest: β_x (e.g. a regression slope).

Problem: The respective explanatory variable \underline{x} was estimated with error:

$$\underline{w} = x + u , \quad u \sim N(0, \sigma_u^2)$$

Lecture 12: Measurement Error 15 / 23

Example of SIMEX use (part 1)

Let's consider a linear regression model

$$y_i = \underline{\beta_0} + \underline{\beta_x} x_i + \underline{\beta_z} z_i + \epsilon_i$$
 , $\epsilon_i = N(0, \sigma^2)$ with

- **y** = $(y_1, \dots, y_{100})^{\top}$: variable with % Bodyfat of 100 individuals.
- $\mathbf{x} = (x_1, \dots, x_{100})^{\top}$ the BMI of the individuals.

Problem: The BMI was self-reported and thus suffers from measurement error. Not x_i was observed, but rather

$$w_i = x_i + u_i$$
, $u_i \sim N(0, 4)$

- $\mathbf{z} = (z_1, \dots, z_{100})^{\top}$ a binary explanatory variable that indicates if the *i*-th person was a male $(z_i = 1)$ or female $(z_i = 0)$.
- \rightarrow Apply the SIMEX procedure!

Lecture 12: Measurement Error

Simulated example

```
set.seed(3243445)
x<- rnorm(100, 24, 4)
w<- x + rnorm(100, 0, 2)
z<- ifelse(x > 25, rbinom(100, 1, 0.7), rbinom(100, 1, 0.3))

y<- -15 + 1.6*x - 2*z + rnorm(100, 0, 3)

data<- data.frame(cbind(w, z, y))
    names(data)<- c("BMI", "sex", "bodyfat")</pre>
```

Lecture 12: Measurement Error 18 / 23

Check out the results

```
Use the error-prone BMI variable to fit a "naive" regression:
r.lm \leftarrow lm(bodyfat \sim BMI + sex, data, x = TRUE)
summary(r.lm)$coef
##
                 Estimate Std. Error t value
                                                     Pr(>|t|)
## (Intercept) -8.003714 2.07060335 -3.865402 2.005407e-04
## BMI
                 1.271558 0.08821382 14.414504 7.478782e-26
## sex
                -1.951735 0.73625960 -2.650879 9.376840e-03
```

Lecture 12: Measurement Error 19 / 23

Now run simex procedure

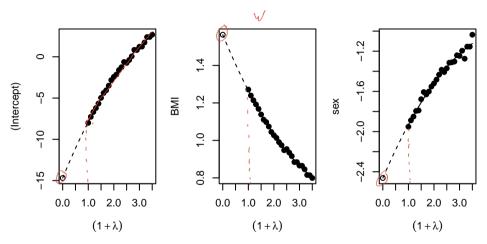

Then run the SIMEX procedure using the simex() function:

```
## Estimate Std. Error t value Pr(>|t|)
## (Intercept) -14.689940 2.6954519 -5.449899 3.825138e-07
## BMI 1.564059 0.1159075 13.494022 5.467540e-24
## sex -2.462127 0.7906688 -3.113980 2.426632e-03
```

Lecture 12: Measurement Error 20 / 23

Graphical results with quadratic extrapolation function:

Note: The sex variable has *not* been mismeasured, nevertheless it is affected by the error in BMI! **Reason:** sex and BMI are correlated.

Lecture 12: Measurement Error 21 / 23

Practical advice

- ▶ Think about measurement error **before** you start collecting your data.
- ldeally, take repeated measurements, maybe of a subset of data points
- Figure out if error is a problem and what the bias in your parameters might be. You might need simulations to find out.
- ▶ If needed, model the error. **Seek help from a statistician!**

G but use your own common serve and domain knowledge as well!
